(54) Title: PROCEDURE FOR MOUNTING AND DISMOUNTING A CLIMBING WALL, AND A CLIMBING WALL

(57) Abstract

The invention relates to a climbing wall, e.g. for outdoor use. The climbing wall comprises a wall part and a structure to which the wall part is attached. The climbing wall consists of at least two climbing sections linked together with a joint, of which the lower section (4) is substantially a fixed part and the upper section (13, 25) can be turned by means of a power means, such as a hydraulic cylinder (8), from a transport position to a climbing position so that the upper section forms an extension of the lower section.

PROCEDURE FOR MOUNTING AND DISMOUNTING A CLIMBING WALL,
AND A CLIMBING WALL

The present invention relates to a procedure as defined
5 in the preamble of claim 1 for mounting and dismounting a
climbing wall and to a climbing wall as defined in the
preamble of claim 3.

Climbing is a sport whose popularity is rapidly growing.
10 Climbing activities are already being organised as compe-
titions and at an amateur level in connection with vari-
ous events, in the courtyards of restaurants and as extra
pursuits at exhibitions. Climbing walls in indoor spaces
are usually fixed structures, but those used in outdoor
15 spaces consist of movable structures that are usually as-
sembled by using modular scaffolding. The drawbacks of
the use of modular scaffolding include slow mounting,
which takes one to two days, and slow dismounting, which
also takes a whole day. As the mounting and dismounting
20 operations require a work force of two or three people,
the use of known climbing walls is also fairly expensive.
A further drawback is that the scaffolding requires
plenty of space and is environmentally unaesthetic.

25 The object of the present invention is to eliminate the
drawbacks mentioned above and to achieve a reliable and
simple climbing wall which can be quickly mounted and
dismounted. The procedure of the invention for mounting a
climbing wall is characterized by what is presented in
30 the characterization part of claim 1. The climbing wall
of the invention is characterized by what is presented in
the characterization part of claim 3. Other embodiments
of the invention are characterized by what is presented
in the other claims.

35

The climbing wall of the invention has the advantages of
ease of use, simplicity and fast and advantageous mount-
ing and dismounting. Mounting and dismounting take only

about 15 minutes, and the supporting structure of the wall is so small that it does not require a large space and has no unaesthetic effect on the environment. As the climbing wall can be quickly mounted and dismounted, it
5 can be erected in several places during the same day. A further advantage is that the climbing tracks can be set up while the wall is in a horizontal position, which makes it considerably easier to set up the tracks. Moreover, as the climbing wall is implemented on the principle
10 of a travelling platform, its transportation is very easy.

In the following, the invention is described by the aid of an application example by referring to the attached
15 drawings, in which

- Fig. 1 presents an axonometric representation of the climbing wall in transport position in an oblique top view,
20 Fig. 2 presents the climbing wall in transport position in lateral view,
Fig. 3 presents the climbing wall in climbing position in lateral view,
Fig. 4 - 6 present the climbing wall in different stages
25 of operation in a simplified lateral view,
and
Fig. 7 present the climbing wall in an alternative climbing position in a simplified lateral view.

30 The climbing wall of the invention is constructed as a travelling platform unit 1, which consists of longitudinal main beams 2 laid on a horizontal plane and a vertical front wall 3 attached to their first ends and a vertical rear wall 4 attached to the other ends of the main
35 beams, the outward-facing back surface of the rear wall constituting the lower part of the climbing wall. The rear wall is fastened to the main beams with trussed bars as exemplified by the numbered bars 16 and 17 in Fig. 1.

Placed on the main beams near each end of the beams are weights 5 consisting e.g. of concrete beams. The purpose of the weights is to stabilize the climbing wall in its climbing position. Placed in a suitable location between
5 the front and rear walls is a supporting frame 6 laid in the same direction with said walls and consisting of horizontal and vertical beams. The supporting frame is additionally fastened to the main beams by means of diagonal struts 7. The structure also comprises a hydraulic
10 unit 22 used as its power unit, driven by normal lighting electricity.

Pivoted on the supporting frame 6 by means of a horizontal joint 9 are hydraulic cylinders 8 which receive their
15 driving power from a hydraulic unit 22 via hydraulic hoses 21. The system preferably comprises two hydraulic cylinders, and these are placed symmetrically with respect to each other on either side of the longitudinal axis of the climbing wall. The piston part 10 of each hy-
20 draulic cylinder is linked with a joint 11 to a longitudinal beam 20 in the trussed structure of the middle section 13 of the climbing wall. The trussed structure additionally comprises other bracing bars, such as cross members 14 and diagonal struts 12. The trussed structure of
25 the middle section 13 of the climbing wall is pivoted on the trussed structure of the rear wall by means of a horizontal joint 15. In the transport position, the middle section 13 of the climbing wall is in a horizontal position, but in the climbing position it is turned up
30 into a substantially upright position and the middle section of the wall is fixed by its trussed structure to the trussed structure of the rear wall 4. The fastening is implemented using securing bolts, by means of which the cross members 16 of the rear wall are fastened to the
35 cross members 14 of the middle section.

The trussed structure 19 of the top section 25 of the climbing wall is pivoted on the trussed structure of the

middle section by means of a horizontal joint 18. In the transport position, the top section 25 of the climbing wall is in an upright position with its top end pointing downwards. The climbing wall is so dimensioned with respect to the main beams that, in the transport position, the top section 25 remains on the inner side of the front wall, i.e. between the front and rear walls, close to the back side of the front wall. Correspondingly, in the climbing position, the top section of the wall is turned up into a substantially upright position with the top end pointing upwards, the top section of the wall being fastened by its trussed structure to the trussed structure of the middle section. The fastening is implemented using securing bolts in the same way as the corresponding attachment between the rear wall and the middle section.

Since the climbing wall of the invention may consist of several sections, e.g. the term 'upper section of the climbing wall' will be used below. This refers to the whole collapsible portion of the climbing wall, which comprises the top section 25 and the middle section 13 but which could also consist of a single continuous part without a separate top section.

The climbing wall is mounted and dismounted as follows: The climbing wall is carried to the site on a truck provided with a transfer table function and then lowered to the ground at a desired location. Electricity to the hydraulic unit 22 is switched on and, using the controls 23, the assembly consisting of the middle section 13 and the top section 25 is raised sufficiently to allow the top section 25 to be turned out so that it forms an extension of the middle section in alignment with the latter, whereupon the top section is fastened to the middle section in the manner described above. If necessary, the climbing track can be set up at this stage by placing the foothold blocks 24 in desired locations. After the track has been set up and the top section fastened to the mid-

dle section as an extension of the latter, the climbing wall is raised completely to an upright position by means of the hydraulic cylinders 8. In the upright position of the wall, the lowest cross members 14 of the middle section lie immediately above the topmost cross members of the rear wall 4 or bottom section and said cross members are tightened against each other by means of securing bolts to ensure the stability of the wall. The climbing wall is now ready for use by climbers. After use, the wall is collapsed into the transport position and lifted onto a truck like a normal travelling platform.

It is obvious to a person skilled in the art that the invention is not restricted to the example described above, but that the embodiments of the invention may instead be varied in the scope of the claims presented below. Thus, the power means may consist of a single high-power hydraulic cylinder or it may consist of one or more pneumatic cylinders, spindle motors, screws, etc. Moreover, instead of using an external lighting electricity supply, it is possible to use the truck's own hydraulic or pneumatic system. If no mains current is readily available, it is possible to use a separate generator. In addition, the position of the wall can be varied. The middle section or the top section of the wall can be turned into a negative angle to make climbing more difficult. Fig. 7 presents an alternative of this type. Furthermore, the height of the top section of the wall can be varied and it is also possible to add a substantially horizontal part to the top end of the top section to represent a ledge. The turning of the top section relative to the middle section 13 can also be implemented by hydraulic or other means, and auxiliary cylinders directed sideways and downwards can be used to hold the whole structure steady.

CLAIMS

1. Procedure for mounting and dismounting a climbing wall comprising a wall part and a structure to which the wall part is attached, characterized in that the mounting portion of the procedure comprises at least the following stages:

- the climbing wall unit, transported to the site on a transport means such as a truck, is lowered from the platform of the transport means to the ground
- the climbing wall is raised to an upright position by means of one or more power means (8) by turning the upper section (13,25) of the climbing wall about a joint (15) between the bottom section (4) and the upper section
- the upper section is locked by its lower end onto the bottom section (4);

and that the dismounting portion of the procedure comprises at least the following stages:

- the locking between the upper section and the bottom section (4) is released
- the upper section of the climbing wall is lowered substantially to its transport position by means of one or more power means (8) by turning the upper section about a joint (15) between the bottom section (4) and the upper section
- the whole assembly is lifted onto the platform of a transport means, such as a truck.

30

2. Procedure according to claim 1, characterized in that the mounting portion of the procedure comprises at least the following stages:

- the climbing wall unit, transported to the site on a transport means such as a truck, is lowered from the platform of the transport means to the ground

- the top section (25) is turned into a desired climbing position relative to the middle section (13) and the top section is locked onto the middle section
- the climbing wall is raised into an upright position by means of one or more power means (8) by turning the combination of the top and middle sections about a joint (15) between the bottom section (4) and the middle section,
- the middle section (13) is locked by its lower end onto the bottom section (4),

and that the dismounting portion of the procedure comprises at least the following stages:

- the locking between the middle section (13) and the bottom section (4) is released
- the climbing wall is lowered substantially to its transport position by means of one or more power means (8) by turning the combined top and middle sections about a joint (15) between the bottom section (4) and the middle section
- the locking between the middle section (13) and the top section (25) is released
- the top section (25) is turned substantially to its transport position
- after the climbing wall has been put back to its transport position, the whole assembly is lifted onto the platform of a transport means, such as a truck.

3. Climbing wall e.g. for outdoor use, said climbing wall comprising a wall part and a structure to which the wall part is attached, **characterized** in that the climbing wall consists of at least two climbing sections linked together with a joint, of which the lower section (4) is substantially a fixed part and the upper section (13,25) can be turned by means of a power means, such as a hydraulic cylinder (8), from a transport position to a climbing position so that the upper section forms an extension of the lower section.

4. Climbing wall according to claim 3, characterized in that the climbing wall assembly is constructed as a travelling platform unit (1) whose basic part consists of
5 main beams (2) and a rear wall (4) attached to the ends of the main beams, the outward-facing back surface of said rear wall constituting the lower part of the climbing wall.
